

Chapter-1

The Earth in the Solar System

Geography = Geography is the study of Earth, its physical features and how human interact with the environment.

Geology Geology is the study of the Earth's surface, rocks, minerals and the processes that shape the Earth over time.

Geomety Geomety refers to the use of mathematical method to study the Earth's shape, size, distance and location.

Gyoid Gyoid is the real shape of Earth, which is slightly irregular and not a perfect sphere.

Celestial bodies Celestial bodies are natural objects like stars, planets, and moon that exist in space. They have their own heat and light. Bodies shining in the night. Some Celestial bodies are very big and hot. They are made up of gases.

Stars Stars are Celestial bodies which have their own heat and light, which they emit in large amounts. The sun is a star.

Mercury - 88 days
Venus - 225 days
Earth -
Mars -

Jupiter -
Saturn -
Uranus -
Neptune -

Pluto
2006
No fixed path

Earth's Twin is Venus
(Size and shape similar)
to Earth

Constellations In the night sky, various patterns are formed by different groups of stars called constellations. Ursa Major or Big Bear is one such constellation.

Planets Planets are celestial bodies that do not have their own heat and light. They are lit by the light of the stars. The word 'planets' comes from Greek word "Planetai" which means 'wanderers' (गलत गलत घूमने वाला).

There are eight planets in our solar system. In order of their distance from the sun, they are: Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus and Neptune.

All the eight planets of the solar system move around the sun in fixed paths. These paths are called orbits.

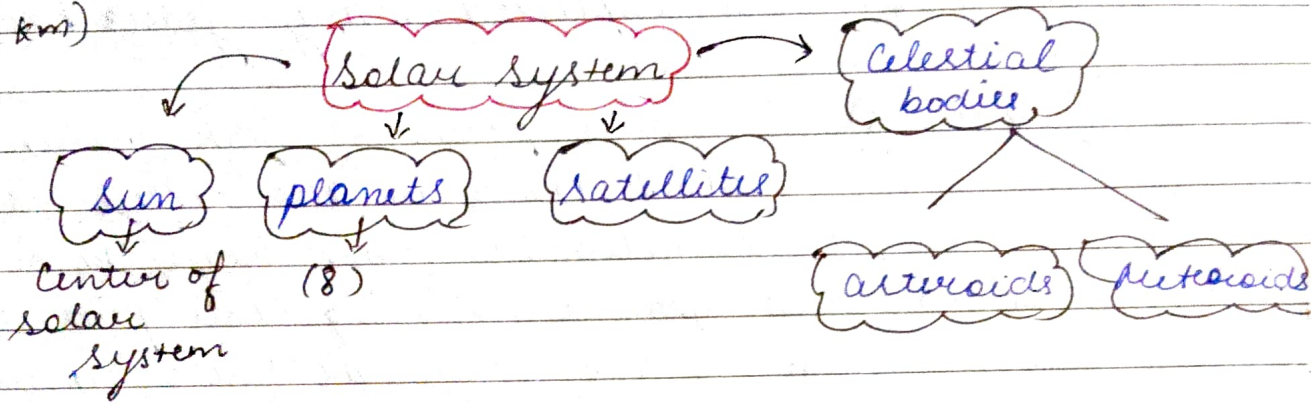

The Solar System The sun, eight planets, satellites and some other celestial bodies known as asteroids and meteoroids form the solar system.

Earth → Solar system → galaxy / Milky way → Universe

The Sun The sun is in the center of the solar system. It is huge and made up of extremely hot gases. It provides the pulling force that binds the solar system. The sun is the ultimate source of heat and light for the

Solar System: The sun is about 150 million km away the Earth.

Earth — Sun
150
million
(150 km)

The Earth have only one satellite called Moon.

Earth → Blue planet (Because of $\frac{2}{3}$ covered by water)

The Earth is the third nearest planet to Sun. In size, it is the fifth-largest planet. It is slightly flattened at the poles.

The shape is describe as a oboid. Conditions favourable to support life are probably found only on the Earth. It was water and air, which are very essential for survival.

The Moon Moon is the Earth's satellite. It appears so big because it is nearer to our planet than Celestial bodies. It is about 3,84,000 km away from us. The moon move around the Earth in about 27 days.

It takes exactly the same time to complete one spin. As a result, only one side of the moon is visible to us on the Earth.

Asteroids Asteroids are tiny bodies that move around the sun. They are found between the orbits of Mars and Jupiter. Scientists are of the view that asteroids are parts of a planet, which exploded many years back.

Meteoroids The small pieces of rock, which move around the sun are called meteoroids. Sometimes, these meteoroids come near the earth and tend to drop upon it. During this process, due to friction with the air, they get heated up and burn.

It causes a flash of light. Sometimes, a meteor without being completely burnt falls on the earth and creates a hollow.

Galaxy A galaxy is a huge system of billions of stars and clouds of dust and gases. There are millions of such galaxies that make the Universe.
